

# Communication base station hybrid energy internal circulation heat dissipation principle

## Overview

---

Its core principle is to use the excellent thermal conductivity of aluminum alloy materials and the integrated molding advantage of die-casting process to achieve the dual functions of structural protection and basic heat dissipation. A literature review is presented on energy consumption and heat transfer in recent fifth-generation (5G) antennas in network base stations. The review emphasizes on the role of computational science in addressing emerging design challenges for the coming 6G technology, such as reducing energy. The continuous improvement in the integration of base station equipment has led to a surge in the number of internal heating elements, with the power of a single sector reaching several kilowatts, far exceeding that of 4G base stations. The measured results showed that the system ran stably, the temperature inside the cabinet was controlled between 12 °C and 39 °C with no high temperature alarm, the compressor running time was significantly reduced, the. Usability-5G base stations use a large amount of heat dissipation, and there are requirements for material assembly automation and stress generated in the assembly process. The system's heat dissipation is getting larger while its size is turning to be smaller. In this case, thermal reliability has.
