

# Solar panel dark current

## Overview

---

Excessive dark current indicates poor wafer quality, such as many surface states, numerous lattice defects, harmful impurities, or overly high doping concentrations. Solar cells made from such wafers usually exhibit low minority carrier lifetimes, directly leading to low efficiency. Distinguishing the characteristics of various currents can identify the cause of abnormal solar panel power and help solve the problem completely. Dark current (DarkCurrent), also known as unilluminated current, refers to the reverse DC current generated when the P-N junction is under reverse bias. There are various types of current inside solar cells, such as dark current, reverse current, and leakage current. These currents have varying degrees of impact on the power output of solar modules. It is crucial for assessing a solar cell's quality and fundamental performance parameters without the need for a solar simulator. The dark I-V measurement procedure does not provide information regarding short-circuit current, but is more sensitive than light I-V measurements in determining the other parameters (series resistance, shunt resistance). With light I-V, we perform the test by illuminating the panel in milliseconds – there is virtually no chance for the array to heat up. Under illumination, small fluctuations in the light intensity add considerable noise.
